04 Alert Triage Validation

1. Alert Triage Simulation

The SOC team monitored the Wazuh SIEM during the simulated adversary emulation. The following alert was identified as a critical priority due to its association with unauthenticated remote command execution.

Alert ID	Description	Source IP	Priority	Status
005	Host-based anomaly detection (rootcheck)	10.0.2.15	High (Level 7)	Resolved

2. Automated Validation and Findings

Upon identifying the suspicious activity, the associated file hashes and IP indicators were cross-referenced with global threat intelligence. This triage process confirmed that the "rootcheck" alert was directly tied to the exploitation of the Samba "username map script" vulnerability.

Summary of Findings:

The alert correctly identified the use of a Metasploit payload. Automated validation via AlienVault OTX confirmed that the technique maps to MITRE T1210 (Exploitation of Remote Services). This triage step prevented "alert fatigue" by allowing the analyst to focus on the high-severity anomaly rather than baseline noise.
